 To overcome computational limitations, we developed a continuous model for meristem distribution and solved it in a semi-Lagrangian framework.

- The whole root matters. But...
- *Meristems* rule plant architecture.

Key to understand the

optimal access to available resources (water, nutrients) and adaptation to the environment (sensing). Hence modelling is of paramount importance to decipher spatial and temporal patterns in plant development.

- To overcome computational limitations, we developed a continuous model for meristem distribution and solved it in a semi-Lagrangian framework.
- Application to a simple case of density dependent growth in coordinated population of plants.

## Models for meristem development in soil

## Deformable domains for plant modelling

- We propose an alternative to classical Eulerian framework (densities defined on nodes of a fixed grid).
- Semi-deformable mesh in radial direction (fluxes in azymuth): densities are computed for a fixed proportion of material (meristems).
- Each meristem distorts its neighbourhood within a domain because of growth. Close meristems have close trajectories. → Sounds adapted to plant roots. Another advantage: few elements to consider.

- Superposition of waves for two different root orders (coupled PDEs).
- Heterogeneity can be modelled *via* non-fixed coefficients.
- Architectural features encoded in source term (e.g.  $b = b_0 \rho_a (u \pm \pi/2)/2$ ).

Conclusion

# Deformable domains allow us to simulate competition in a population of plants

- 1. Start from each meristem that has a domain distorting trajectory.
- Several independent (similar self-avoiding) domains to model a plant.
- Allocated resources depend on relative densities. Dynamics models simplistic competition.

### Conclusion Summary and perspectives Some reading

(日) (同) (日) (日)

- Development of the plant can be viewed as (overlapping) waves of meristems; root architecture = footprint of these waves.
- Simple models with quick computation allows us to obtain interpretation in terms of root developmental mechanisms.
- Deformable domains (Lagrangian solver) for the simulation of ensemble of plants complementary to static mesh approach (Eulerian solver). Application in ecology ?

## Future Work

- Models in early stage of development so produce useable package (+ stochasticity, plant/environment feedbacks ...).
- More experiments to characterize wave morphology, influence of genotype, developmental processes, *etc.*
- Link this kind of study to genome. In a population with different genotypes, a mapping (stat. link) is not enough.
   Dynamic (not only accouting for final skeleton) model where traits (QTL context) would be developmental precesses.
